54 **Data input apparatus.**

57 Data input apparatus (100) operative to store and to transfer written information includes a pen (104) and a board (102), which has a sensing mechanism (101), a memory device (106) and a communication link (112). When the pen (104) imprints symbols to the board (102), the symbols are not concurrently electronically displayed. But the symbols are detected by the sensing mechanism (101), stored in the memory device (106), and can later be transferred to an electronic device (150) through the communication link (112).

**FIG. 1**

**EP 0 655 674 A2**

The present invention relates to data input apparatus, for example an electronic board for storing and transferring information.

One constantly has to deal with different types of forms. For example, a government employee has to fill out administration forms, an applicant has to fill out application forms, and a warehouse owner has to fill out inventory forms. The information in the forms usually has to be filed or stored in a computer by an operator for later use. Many people have designed different devices to streamline such processes.

In one prior art design, a user writes directly on an electronic device with a screen. The written information is concurrently shown on the screen, and is also stored in the electronic device. This approach could be quite expensive due to the cost of the screen. Moreover, the device with a screen may be quite fragile, and may not be suitable to be used in a hostile environment.

In another prior art design, a user writes on an electronic pad with a computer connected to the pad. The computer shows and stores the written information. This approach could again be quite expensive.

Thus prior methods either require a user to fill out a form and an operator to input the information into a storage device, or solve the problems in an expensive manner with pads and screens.

The present invention seeks to provide improved data input apparatus.

According to an aspect of the present invention, there is provided data input apparatus as specified in claim 1.

According to another aspect of the present invention, there is provided a method of inputting a device into a device as specified in claim 11.

The invention can provide in some embodiments a low-cost electronic board, which can solve problems of recording and transferring information even in a hostile environment. The board can be of low-cost and durable.

In the preferred form, all that is required is for the user to write the information on paper on top of an electronic board. The written information will be automatically stored in the board. The user, ignoring the electronics in the board, is just using the board as a support, as one normally does when one is filling out a form or taking notes.

The invention preferably includes a pen and a board that includes a sensing mechanism, a memory and a communication link. When symbols are coupled to the board through the pen, the symbols are not concurrently displayed electronically, but are detected by the sensing mechanism and stored in the memory. The symbols can also be transferred to another electronic device through the communication link for further manipulation, such as displaying the symbols.

An embodiment of the present invention is described below, by way of example only, with reference to

the accompanying drawings, in which:

Figure 1 is a perspective view of a first preferred embodiment data input board;

Figure 2 shows an underside view of the data input board of Figure 1;

Figure 3 is an exploded view showing the component parts inside of first preferred embodiment of data input board;

Figure 4 shows a few process steps describing different operations in the first preferred embodiment;

Figure 5 shows an example of form for use with the data input board of Figure 1;

Figure 6 shows a second preferred embodiment of data input board; and

Figure 7 shows a third preferred embodiment of data input board.

Figure 1 shows a perspective view of a first preferred embodiment 100 of the invention, and Figure 2 shows its underside view. The embodiment 100 includes a board 102 and a stylus, such as a pen 104. Figure 3 shows some of the parts inside the first preferred embodiment 100, and Figure 4 shows a few process steps describing different operations in the first preferred embodiment 100.

The board 102 preferably works on rechargeable batteries 136 stored inside the board, which has an AC power jack 132 for charging the batteries. In another embodiment, dry batteries may be used or the board may be connected to an external power supply.

The board 102 preferably does not have an on/off switch. Normally, the board is in a standby or listening mode 175, so as not to deplete the batteries. During the standby mode 175, preferably, there is an electronic clock running inside the board 102 for indicating time and date.

Preferably, the board is automatically activated 177 when the tip of the pen 104 is in close proximity to the board 102. In the first embodiment, the board 102 includes a digitizing tablet 138, with a sensing mechanism 101 constantly generating an electromagnetic field. Once the tip of the pen 104 is in close proximity to the board 102, the electromagnetic field senses the tip, and the board is activated. Thus, the board has an automatic power activation mechanism; it activates the board 102 when the sensing mechanism 101 senses the tip of the pen 104. So, the embodiment does not need a separate power on/off switch. Such a mechanism is disclosed, for example, in "Wacom Tablets Keep Their Edge," written by Bishop, published in MacWeek, April 20, 1992, and should be evident to those skilled in the art.

The location of the tip of the pen is also registered by the sensing mechanism 102, and stored, 179, in a memory device 106 in the board. The memory device 106 may be a memory chip inside the first embodiment 100 or may be a removable card, such as a PCMCIA card, or both.

Another preferred mechanism to activate the board is to have an active pen constantly radiating an electromagnetic field, and sensors in the board constantly listening. When the tip of the active pen is in close proximity to the board, the board picks up the electromagnetic field from the pen, and is automatically activated, with the location of the tip of the pen registered and stored in the memory device 106.

A further preferred mechanism uses pressure sensors as the sensing mechanism. Many pressure sensors are positioned below the top surface of the board. When the user writes, the pen presses onto the board to activate the sensors and the board. The position of the tip of the pen is also registered and stored in the memory device 106.

When the first embodiment is in its standby mode, it is constantly listening for interrupts. One such interrupt occurs, as described above, when the tip of the pen 104 is in close proximity to the board 102. Another type of interrupt is indicated by positioning, 181, a piece of paper on the board, 102, for imprinting symbols.

To record information with the first embodiment 100, the user probably picks up the board 102 and a piece of paper, such as the form 200 shown in Figure 5. Then the user performs certain operations that may directly or indirectly create an indication that the form has been positioned on the board 102.

One such indication is through activating, 183, a holding mechanism 114 on the board 102 to hold onto the form 200. This holding mechanism 114 may be a clip pressing onto the board. There is preferably a sensing device 116 under the clip 114, which senses the pressure of the clip 114. This sensing device 116 may be a pressure sensor. Once the pressure from the clip 114 is below a certain level, an interrupt is generated and a tick-mark is stored in the memory 106 to indicate that there may be a new form positioned on the first embodiment. The time and date on the clock are preferably also stored in the memory 106 with the tick-mark. If the user just plays with the clip 114 by pressing it many times, preferably, every time the clip is pressed, its tick-mark overrides its prior tick-mark. Once the tip of the pen 104 is in close proximity to the board, 102, the tick-mark stored will not be overridden, but will be permanently stored in the memory 106. The first embodiment preferably includes the clip, but other holding mechanisms without any movable parts may be used, such as small lips positioned on the edges of the board.

Another indication method is through an identifier mechanism on the board 102. The form 200, preferably, has an identifier, such as a form number 202; for example, a number 5 designates an inventory form for GM cars and a number 6 designates a bankcheck. The user may store this form number in the memory 106 through one type of identifier mechanism, which is a switch 120. Every time the switch is pressed or

activated, 185, an indication is generated to show that a new form may have been positioned on the board. Moreover, pressing the switch also generates different identifiers on a display, such as a liquid crystal display (LCD) 128. These identifiers were pre-stored in the memory 106 for identifying different types of forms. When the right identifier is shown, such as GM cars, the user stops pressing the switch. The right identifier or its representation is stored, 187, in the memory 106 when the tip of the pen 104 is in close proximity to the board 102.

Another type of switch is a toggle switch; every time the switch is toggled, again a different identifier is shown on the LCD. If the switch is not toggled, the first embodiment presumes that the identifier of the new form is the same as its prior form.

In another preferred embodiment, the form 200 has a bar-code 204, which is read by a bar-code reader 118 in the embodiment. The bar-code reader 118 may be under the clip 114. The reader automatically reads the bar-code 204 once the interrupt from the clip 114 is received.

After securing the form 200 to the board 102, the user picks up the pen 104, which may be stored inside a slot 130, and starts imprinting symbols, taking notes or writing onto the form with the pen 104. While the user is imprinting symbols or taking notes, all the symbols or the pen strokes are stored in the memory device. Note that the pen does not have to touch the board; as long as the tip of the pen is in close proximity to the board, the location of the tip will be registered by the board and stored in the memory device 106.

The storing function is transparent to the user. The user just fills out the form or takes notes on a piece of paper with the board as a support, as one normally does in writing. The user does not have to activate the board. She simply picks up the board and starts writing, and the information will be automatically stored in the board.

There may be many forms under the clip 114 on the board 102. The user may be flipping back and forth writing onto different forms without activating the clip 114. Different methods may be used to indicate, 189, that a new form is being used. In one example, a sound receiver is incorporated in the board, and the clip 114 holds onto a checkbook. When the user finishes filling out a check, the user may tear it out of the checkbook. The perforation sound activates an interrupt indicating that the user may be writing on a new check next time the board is used. This indication is stored in the memory 106. Other types of sound may be used for indication. Another indication method is to have a small printed box, 206, on the form; a different form has a box at a different position. Before writing onto the form, the user puts a checkmark in the box, which is used to identify the form, and the identification is stored in the memory.

When the user is ready to transfer all the stored information into another electronic device 150, such as a computer or a printer, the user may remove the PCMCIA card, and put it into the other electronic device. Another mechanism to pass the information is through a communication link 112. When the user presses a transfer switch 140, an interrupt is activated, 191, to command the transfer of data. At this point, the stored information is ready to be automatically transferred, 193, through the link 112 to the electronic device. The information would not be transferred until a hand-shaking signal is sent from the electronic device 150 and received by the preferred embodiment, indicating that the electronic device 150 is ready to receive the information.

One form of communication link 112 is a remote link, such as an infra-red link, a microwave link or a radio link, with a transmitter 108 and a receiver 110. The receiver 110 may also be used to modify the software stored inside the board 102. If the infra-red link is used, the electronic device receiving the infra-red signal should be in close proximity to the preferred embodiment 100. Another form of communication link 112 is through an RS-232 serial port 113 or an ethernet port or other means to communicate with the electronic device.

The other electronic device 150, such as a computer, receives, for example, the form number and the written information. The computer can retrieve the same type of form from its own memory. The written information can then be re-displayed on the computer at approximately the corresponding positions of the form where the information was filled in.

In the first preferred embodiment, the board preferably includes a functionality indicator 142 and an activity indicator 146. The functionality indicator 142 should be conspicuous and may be a red light-emitting diode or an electronic beep. In another embodiment, the functionality indicator 142 may be a specific digit on the LCD 128. The functionality indicator will automatically generate an interrupt signal if there is a functionality problem when the embodiment is activated. Functionality problems include the batteries being low in power, the embodiment being low in unused memory, the embodiment malfunctioning or the electronic device 150 receiving the transferred information not ready to communicate. When a functionality problem occurs, the problem is preferably described on the LCD 128.

The activity indicator 146 is preferably at a position on the LCD 128. It may be a letter displayed on the LCD. The letter shows up on the display when the board 102 is collecting and storing written information. If the pen 104 is not in close proximity to the board 102 or if the pen 104 is malfunctioning so that the written information is not captured, the letter will not show up on the display.

The first embodiment 100 includes a top 152 and

a bottom 154 cover. The embodiment 100 is quite rugged and can be used in very hostile environments. With either no movable part or rugged movable parts, such as the clip, and no fragile components, such as glass on a screen, the embodiment can be tossed and thrown around, or kneeled on, without affecting the functionality of the embodiment.

In another embodiment, the board is similar to the first embodiment, except it does not have a driver for a PCMCIA card, and it may not have an RS-232 serial port. In this embodiment, the board is waterproofed, and can be used underwater. In this embodiment, one does not use paper, but may use a mechanism similar to a "Magic Slate," and write on a piece of plastic. The "Magic Slate" may be similar to the one disclosed in U.S. Patent Number 5,133,554, titled, "Lotto Ticket Card Holder."

Figure 6 shows a second preferred embodiment 275 of the present invention. It is similar to the first embodiment except that a board 277 similar to that of the first embodiment is in a folder 279 with a cover 281.

Figure 7 shows a third preferred embodiment 300 of the present invention. This embodiment 300 includes a pen 302 and a watch 304. The watch 304 has a board 306, similar to the board in the first embodiment, embedded in it. When information is written onto the board by the pen, the information is stored in a memory device inside the board as in the first embodiment. The information written is not displayed on the watch, and can be removed from the watch and transferred to an electronic device using a communication link. One can use this embodiment, for example, to write down a phone number while one is on the run.

The implementation of the accessories with the described boards, such as the bar-code reader 118, the pressure sensor 116, the infra-red link, the microwave link, the radio link, the waterproofed covers or the active pen constantly radiating an electromagnetic field to be captured by a board, should be evident to those with ordinary skill in the art and will not be further described in this specification.

From the foregoing it will be appreciated that a low-cost and a rugged electronic board has been described which can store and transfer written information. Other embodiments will be apparent to the skilled person.

The disclosures in United States patent application no. 08/159,279, from which this application claims priority, and in the abstract accompanying this application are incorporated herein by reference.

## Claims

1. Data input apparatus comprising:  
a stylus (104) for defining symbols;

a board (102) on which symbols can be formed by means of stylus, the symbols not being concurrently displayed electronically;

a sensing mechanism (101) coupled to the board (102) for sensing the formed symbols; and

a memory device (106) coupled to the board (102) for storing the sensed symbols for later transfer.

receiving the symbols by a board;

sensing the symbols received by the board, but not concurrently electronically displaying the symbols; and

storing the symbols in the board for later transfer.

2. Data input apparatus as recited in Claim 1, comprising a communication link (112) for transferring the symbols stored in the memory (106). 10
3. Data input apparatus as recited in Claim 1 or 2, comprising a holding mechanism (114) operative to hold a piece of paper (200) or other mechanism onto the board (102). 15
4. Data input apparatus as recited in Claim 3, comprising a sensor (116) operative to produce a signal when the holding mechanism (110) is activated. 20
5. Data input apparatus as recited in Claim 3 or 4, wherein the paper or other mechanism is a standard form (200) with an identifier (202,204,206); the apparatus comprising an identifier mechanism (118,120) for storing the identifier (202,204,206) in the memory device (106). 25
6. Data input apparatus as recited in any preceding Claim, comprising a functionality indicator (142) alerting a user to check the functionality of the apparatus (100). 30
7. Data input apparatus as recited in any preceding Claim, comprising an automatic power activation mechanism (104,101) operative to activate the apparatus (100) when the sensing mechanism senses the tip of the stylus (104). 35
8. Data input apparatus as recited in any preceding Claim, comprising an activity indicator (146) operative to provide an indication when symbols are provided on the board (102) and stored in the memory device (106). 40
9. Data input apparatus as cited in any preceding Claim, wherein the board (306) is in the form of a watch (304). 45
10. Data input apparatus as recited in any preceding Claim, wherein the apparatus (100) is waterproofed. 50
11. A method of inputting data into a device comprising the steps of: 55
  - forming symbols by a stylus;
